

The same connectome at four scales, one rendering

phase-5 grouping; drawn as points (16k somata sit below the shared density scale)

10x

1,392,550 neurons · 27,842,102 connections

the real brain: FlyWire v783 somata, 139,241 of 139,255 placed

100x

13,924,100 neurons

subdivided ladder top rung (10 children per soma)

Vyb/CUDA kernels: at this density the cloud is a silhouette

1x, 10x and 100x are the device rasters from the Vyb NVPTX kernels in src/vyb_kernels/upscale_kernel.vyb (one atomic add per soma), not a re-plot.

All four panels share one density scale (log counts per 28 nm pixel, ceiling 24), so a brighter panel is a denser one; every panel is scaled to its own extent, so what changes across the poster is point density, not framing. Mean degree stays ~19 partners per neuron at every scale.

100x is real data: 13,924,100 somata from 139,255 parents, each child placed within its parent's local spacing, then rasterized at 28 nm per pixel. 13.9M somata fill every pixel they touch, which is why the panel reads as a white silhouette —

see [results/scale-gallery/zoom-100x.html](https://results.scale-gallery/zoom-100x.html) (or zoom-100x.png) to resolve individual neurons at full resolution.
